Mycofloristic studies in deciduous oak-woods in the province of Siena (Tuscany, Italy)

Abstract

Salerni, E., Laganà, A., Barluzzi, C., De Dominicis, V. & Perini, C.: Mycofloristic studies in deciduous oak-woods in the province of Siena (Tuscany, Italy). — *Fl. Medit.* 8: 93-133. 1998. — ISSN 1120-4052.

Mycofloristic investigations, carried out in the deciduous oak-woods in the western part of the province of Siena (Italy), led to the identification of 389 fungi, 74 of which new for the province. The taxa are listed following the fungal classification of Hawksworth & al. (1995).

The deciduous oak-woods of an area going from Monteriggioni, a middle-age village, to the River Farma in the province of Siena, have been observed in order to increase the mycofloristical knowledge.

On the basis of climate, geological substratum and past human activities two different zones can be distinguished: one north of the River Rosia (Area A), the so-called "Montagnola Senese", and the other to the south, near Monticiano, a village between the Rivers Farma and Rosia (Area B) (Fig. 1).

Following Thornthwaite's classification, the climate can be generally defined as mesothermic, subhumid-humid (Barazzuoli & al. 1993). The annual average temperature is 13.5 °C and rainfall is between 850-950 mm/year on the "Montagnola Senese", while it is 14.3 °C and 1160 mm/year in the Monticiano area.

The geolithological substratum is principally composed of limestone in the area A and of "verrucano", a siliceous rock, in B.

The "Montagnola Senese" was in the past intensively exploited by man. The result of this activity is a puzzle given by castles, ancient villages, churches and monuments, cultivated fields and woods. The latter are characterized by abrupt changes from evergreen to deciduous oak-forests and chestnut coppices showing the selection of specific trees. The landscape, south of the River Rosia is different: except for a few villages and a narrow strip of cultivated fields the landscape turns wilder.

The Woods are not restricted to rocky slopes, but dominate the whole area reaching the fluvial plains. These natural conditions allowed the survival of several biotypes of great importance.

The deciduous oak-woods observed in both areas are given by coppices in which the commonest tree is *Quercus cerris*.

However, dominant trees vary according to substratum, microclimate and human activity.

In the forests of the "Montagnola Senese" *Q. cerris* is accompanied by *Q. pubescens*, *Fraxinus ornus* and *Ostrya carpinifolia*.

Cornus mas, *Ligustrum vulgare* and *Pyracantha coccinea* are present in the shrub-layer, while *Helleborus bocconei*, *Geranium sanguineum* and *Buglossoides purpureo-caerulea* can be cited for the herbaceous one. On these calcareous soils it is possible to find samples of *Q. ilex*.

On the other hand in the Monticiano area *Q. cerris* is accompanied by *Q. petraea* and aciphilous species such as *Castanea sativa*, *Pteridium aquilinum*, *Erica scoparia* and *Calluna vulgaris*. The mycological observations were carried out from 1992 to 1996. The classification of fungal species follows Hawksworth & al. (1995), while the nomenclature follows mainly Arnolds & al. (1995); for some species (marked with *) several publications, cited within brackets, were used.

Synonyms were sometimes reported to avoid misunderstandings. The authors' names of fungal species are abbreviated according to Powell & al. (1992).

Yet for each species the trophic group is indicated: **M** (mycorrhizal species), **Sh** (saprotroph on humus), **Sl** (saprotroph on litter), **Sw** (saprotroph on wood), **Sc** (saprotroph on dung), **Li** (lichenized). Species never published up to now for the province of Siena are indicated with ★.

The following mycofloristic list reports 389 taxa, 74 of which new for the Sienese province. 105 taxa have been found only in the area A, 90 only in the area B and the remaining 194 are common for both areas.

Note: the samples have been determined as *P. semibulbosus* by means of Orton (1986).

The nomenclature of Arnolds & al. (1995) has however been followed in accordance with Vellinga & Schreurs (1985) who, after studying several exsiccata from different parts of Europe, have come to the conclusion that *P. plautus* is an extremely variable species. "... it is not been possible to divide this taxon in discrete units, due to the many transitions in important characters as colour of the pileus, shape and size of the elements and the Q of the spores ..." (Vellinga 1990).
